

SEDAR 66 South Atlantic Tilefish (Golden)

From the previous assessment (2016 Update)

- Re-examine the quantity and quality of biological samples collected by "Other" commercial gears. If
- adequate, consider methods for inclusion.
- Monitor the quantity of commercial and recreational discards and consider methods for inclusion if deemed
- necessary.
- More closely examine historical length composition data used in the assessment and consider alternate methods for incorporating this information in the model.

From the current assessment (SEDAR 66)

- Explore alternative distributional assumptions for natural mortality M for MCBE uncertainty analysis.
- Consider incorporation of new fishery independent abundance data and/or life history data from: CRP
- Coop Bottom longline survey data, deepwater survey data, SCDNR vertical longline survey, SA Deepwater longline Survey
- Reconsider evidence for stock structure (i.e. potential for a north/south split)
- Increase age sampling to improve composition data
- Investigate effects of weather/oceanographic patterns on catchability. Due to the derby style nature of
- the fishery, the fleet tends to operate in less than ideal conditions which may affect catchability and fishery-dependent CPUE.
