

SEDAR 89 South Atlantic Tilefish**1. From the previous assessment (SEDAR 66)**

- (a) Re-examine the quantity and quality of biological samples collected by "Other" commercial gears. If adequate, consider methods for inclusion.
- (b) Monitor the quantity of commercial and recreational discards and consider methods for inclusion if deemed necessary.
- (c) More closely examine historical length composition data used in the assessment and consider alternate methods for incorporating this information in the model.
- (d) Collect data to investigate the stock structure of tilefish in the Atlantic ocean through a multifaceted approach (e.g., genetics, meristics, diet, otolith chemistry, life history characteristics, etc.)
- (e) Increase age sampling to improve composition data

2. From the current assessment (SEDAR 89)

- (a) following the guidance of the SADLS review, incorporate the fishery-independent standardized index of abundance and associated age composition
- (b) Investigate potential mechanisms for the domed selectivity that started in 2020
- (c) Collect and process more histological samples to reduce the uncertainty in the batch fecundity estimates to provide better estimates of SSB.
